

A dark blue vertical bar on the left side of the slide.

Spring Boot & REST

A light blue vertical bar on the left side of the slide.

Spring Boot

- When deploying to the cloud it's easier to have a **single executable** to deploy
- Spring Boot aims to facilitate this:
 - Create a full application in one executable JAR
 - Including embedded Tomcat Web Server
 - Make it quick and easy to create such applications
 - Using **convention over configuration**

Opinionated View

- The official documentation says Spring Boot takes “an opinionated view of the Spring platform and third party libraries so you can **get started with minimal fuss**”
- These opinions are the conventions
 - So you have to do less configuration

Do less and
accomplish more

Why not Earlier in the Course?

- Although Spring Boot is awesome
 - It **hides the details** of what is going on
- So far we've manually configured everything
 - So that you know how they work
 - If it breaks you are better equipped to fix things

Typical Spring Boot POM

```
<?xml version="1.0" encoding="UTF-8"?>
<project xmlns="http://maven.apache.org/POM/4.0.0" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://maven.apache.org/POM/4.0.0 http://maven.apache.org/xsd/maven-4.0.0.xsd">
  <modelVersion>4.0.0</modelVersion>

  <groupId>edu.mum.cs544</groupId>
  <artifactId>demo</artifactId>
  <version>0.0.1-SNAPSHOT</version>

  <parent>
    <groupId>org.springframework.boot</groupId>
    <artifactId>spring-boot-starter-parent</artifactId>
    <version>2.1.5.RELEASE</version>
  </parent>
  <dependencies>
    <dependency>
      <groupId>org.springframework.boot</groupId>
      <artifactId>spring-boot-starter-web</artifactId>
    </dependency>
  </dependencies>
  <build>
    <plugins>
      <plugin>
        <groupId>org.springframework.boot</groupId>
        <artifactId>spring-boot-maven-plugin</artifactId>
      </plugin>
    </plugins>
  </build>
</project>
```

Inherit POM config from
Spring Boot

Typical dependencies
for a web application

Package as an
executable jar file

Spring Boot Starters

Table 13.1. Spring Boot application starters

Name	Description	Pom
<code>spring-boot-starter</code>	Core starter, including auto-configuration support, logging and YAML	Pom
<code>spring-boot-starter-activemq</code>	Starter for JMS messaging using Apache ActiveMQ	Pom
<code>spring-boot-starter-amqp</code>	Starter for using Spring AMQP and Rabbit MQ	Pom
<code>spring-boot-starter-aop</code>	Starter for aspect-oriented programming with Spring AOP and AspectJ	Pom
<code>spring-boot-starter-artemis</code>	Starter for JMS messaging using Apache Artemis	Pom
<code>spring-boot-starter-batch</code>	Starter for using Spring Batch	Pom
<code>spring-boot-starter-cache</code>	Starter for using Spring Framework's caching support	Pom
<code>spring-boot-starter-cloud-connectors</code>	Starter for using Spring Cloud Connectors which simplifies connecting to services in cloud platforms like Cloud Foundry and Heroku	Pom
<code>spring-boot-starter-data-cassandra</code>	Starter for using Cassandra distributed database and Spring Data Cassandra	Pom
<code>spring-boot-starter-data-cassandra-reactive</code>	Starter for using Cassandra distributed database and Spring Data Cassandra Reactive	Pom
<code>spring-boot-starter-data-couchbase</code>	Starter for using Couchbase document-oriented database and Spring Data Couchbase	Pom
<code>spring-boot-starter-data-couchbase-reactive</code>	Starter for using Couchbase document-oriented database and Spring Data Couchbase Reactive	Pom
<code>spring-boot-starter-data-elasticsearch</code>	Starter for using Elasticsearch search and analytics engine and Spring Data Elasticsearch	Pom
<code>spring-boot-starter-data-jpa</code>	Starter for using Spring Data JPA with Hibernate	Pom
<code>spring-boot-starter-data-ldap</code>	Starter for using Spring Data LDAP	Pom
<code>spring-boot-starter-data-mongodb</code>	Starter for using MongoDB document-oriented database and Spring Data MongoDB	Pom
<code>spring-boot-starter-data-mongodb-reactive</code>	Starter for using MongoDB document-oriented database and Spring Data MongoDB Reactive	Pom
<code>spring-boot-starter-data-neo4j</code>	Starter for using Neo4j graph database and Spring Data Neo4j	Pom
<code>spring-boot-starter-data-redis</code>	Starter for using Redis key-value data store with Spring Data Redis and the Lettuce	Pom

- There are many starters to choose
- You can also combine starters
- And add your own additional deps

Version Numbers

- Best **not to give a version** to dependencies
- Spring Boot has will automatically select the best version to work with (based on parent)

```
<!-- needed for Spring MVC -->
<dependency>
  <groupId>org.springframework.boot</groupId>
  <artifactId>spring-boot-starter-web</artifactId>
</dependency>
<!-- needed for JSP -->
<dependency>
  <groupId>org.apache.tomcat.embed</groupId>
  <artifactId>tomcat-embed-jasper</artifactId>
</dependency>
<dependency>
  <groupId>javax.servlet</groupId>
  <artifactId>jstl</artifactId>
</dependency>
```

No version on any
dependency

Code & Config

- Make a class with a **main()** your **@Configuration**
 - Spring boot prefers Java Config
 - Spring boot requires a main() method
 - Starts your Spring Boot application

```
@Configuration  
@ComponentScan  
@EnableAutoConfiguration  
@EnableWebSecurity  
public class Application {
```

Spring Boot annotation to have it look through your JARs and configure it self based on what it finds

```
    public static void main(String[] args) {  
        SpringApplication.run(Application.class, args);  
    }  
}
```

SpringApplication.run() is a Spring Boot method that requires the name of your primary configuration class and starts the application

@SpringBootApplication

- @SpringBootApplication is a **composite** of:

- @Configuration
- @ComponentScan
- @EnableAutoConfiguration

Since all Spring Boot applications generally need all 3, might as well create a single composite

```
@SpringBootApplication
@EnableWebSecurity
public class Application {

    public static void main(String[] args) {
        SpringApplication.run(Application.class, args);
    }
}
```

Properties or YML

- Auto-configuration can't do everything
 - **Needs certain values** such as DB user / password
- These values can be stored in:
 - application.properties

Inside your resources dir

Examples

```
spring.datasource.url = jdbc:mysql://localhost/cs544  
spring.datasource.username = root  
spring.datasource.password = root
```

application.properties

```
spring.jpa.properties.hibernate.dialect = org.hibernate.dialect.MySQL5Dialect  
spring.jpa.hibernate.ddl-auto = create-drop
```

```
spring.mvc.view.prefix=/WEB-INF/views/  
spring.mvc.view.suffix=.jsp
```

```
logging.level.root=DEBUG
```

Additional Configuration

- Autoconfig takes care of most things
 - But if needed **you can add / override** config
- Can be in main or in extra config files:
 - @Import to include @Configuration files
 - @ImportResource can include XML config files

Profiles & External Configuration

- Spring Boot has **profile support**
 - Parts of your internal (in-project) configuration are active only in certain environments (dev / test / production / ...)
- External config can be picked up in many ways
 - To indicate which environment you are in
 - Or to overwrite internal config values

Profiles

- Multiple profiles can be active, indicated by:

```
spring.profiles.active=dev,mysql
```

- Then includes profile specific properties files:

```
application-dev.properties  
application-mysql.properties
```

- And activates configuration annotated for it

```
@Configuration  
@Profile("production")  
public class ProductionConfiguration {
```

External Config Options

- 1) Devtools global settings properties on your home directory (`~/spring-boot-devtools.properties` when devtools is active).
- 2) `@TestPropertySource` annotations on your tests.
- 3) `properties` attribute on your tests. Available on `@SpringBootTest` and the test annotations for testing a particular slice of your application.
- 4) Command line arguments.
- 5) Properties from `SPRING_APPLICATION_JSON` (inline JSON embedded in an environment variable or system property).
- 6) `ServletConfig` init parameters.
- 7) `ServletContext` init parameters.
- 8) JNDI attributes from `java:comp/env`.
- 9) Java System properties (`System.getProperties()`).
- 10) OS environment variables.
- 11) A `RandomValuePropertySource` that has properties only in `random.*`.
- 12) Profile-specific application properties outside of your packaged jar (`application-{profile}.properties` and YAML variants).
- 13) Profile-specific application properties packaged inside your jar (`application-{profile}.properties` and YAML variants).
- 14) Application properties outside of your packaged jar (`application.properties` and YAML variants).
- 15) Application properties packaged inside your jar (`application.properties` and YAML variants).
- 16) `@PropertySource` annotations on your `@Configuration` classes.
- 17) Default properties (specified by setting `SpringApplication.setDefaultProperties`).

Command Line

Specifying Profile(s)

- You can start a Spring Boot application as:

```
java -jar app.jar --spring-profiles-active=prod
```

- Or you can set a environment variable

```
SET SPRING_PROFILES_ACTIVE=prod
```

```
java -jar app.jar
```

Running

- During development run it in your IDE

- Or from its own Maven target

\$mvn spring-boot:run

- Include Spring **Boot DevTools**

Will not affect production env.

- Not included when packaging the JAR

```
<!-- automatically reloads app when development files change -->
<dependency>
  <groupId>org.springframework.boot</groupId>
  <artifactId>spring-boot-devtools</artifactId>
  <optional>true</optional>
</dependency>
```

Optional makes it not go into JAR

Dev Tools Benefits

- Automatically **restarts** when it senses a change
 - On restart logs changes to autoconfig
- Option to configure resources:
 - That should not trigger a restart when changed
 - Or watch files outside the project that should trigger

Banner

Not practical, but kind of fun

- When starting Spring Boot shows a banner

- Customize the banner by adding to resources dir:
 - **banner.txt** (or .jpg, .gif, .png)
 - Or set spring.banner.location
 - Or turn it off with spring.main.banner-mode: off

Images are converted to ASCII

Summary

- Spring Boot uses convention over configuration
 - Use property for remaining values
- Provides dependency management through starters
 - You never specify version numbers
- Uses a `@SpringBootApplication` with a `main()` method
 - Which invokes `SpringApplication.run()`
- Has support for multiple configuration profiles
 - That can be activated through external configuration

Integration

CS544 EA

REST

Remote Invocation

- There are many forms of Remote Invocation
 - CORBA, RMI, XML-RPC, SOAP, ...
 - Web services can be seen as remote invocation
- The most popular form of WebService today are **RESTful webservices**

Web Service

- A web service offers functionality that can be called by clients using standard protocols
- **RESTful** web services use **HTTP**
 - Are officially payload (data) agnostic
 - Most popular data format: **JSON**

HTTP

- With web pages we use GET and POST
 - GET to retrieve
 - POST to insert / update data
- RESTful uses **more HTTP methods**:
 - GET to *retrieve* data
 - POST to *create* (a new URI is assigned)
 - PUT to *replace* data at a URI
 - PATCH to *update* or *create* data at a URI
 - DELETE to *delete* data and its URI

JSON

- The JavaScript Object Notation

- Created by Douglas Crockford
JavaScript: the Good Parts
- Human readable
attribute / value pairs
- A lightweight alternative to XML

```
{  
  "firstName": "John",  
  "lastName": "Smith",  
  "isAlive": true,  
  "age": 27,  
  "address": {  
    "streetAddress": "21 2nd Street",  
    "city": "New York",  
    "state": "NY",  
    "postalCode": "10021-3100"  
  },  
  "phoneNumbers": [  
    {  
      "type": "home",  
      "number": "212 555-1234"  
    },  
    {  
      "type": "work",  
      "number": "212 555-4567"  
    }  
  ],  
  "emails": [  
    {  
      "type": "work",  
      "email": "john.smith@company.com"  
    },  
    {  
      "type": "home",  
      "email": "john.smith@gmail.com"  
    }  
  ],  
  "pets": [  
    {  
      "name": "fluffy",  
      "type": "cat",  
      "age": 3  
    },  
    {  
      "name": "max",  
      "type": "dog",  
      "age": 4  
    }  
  ],  
  "favoriteFoods": [  
    "hamburger",  
    "ice cream",  
    "pasta"  
  ]  
}
```

Spring MVC

- Spring MVC built-in support for RESTful web services

```
<dependency>  
    <groupId>com.fasterxml.jackson.core</groupId>  
    <artifactId>jackson-databind</artifactId>  
</dependency>
```

- When the Jackson library is on the classpath
 - Automatically configures the bean:
MappingJackson2HTTPMessageConverter
 - Able to convert Java Objects to JSON text
 - Able to convert JSON text to Java Objects

@RestController is a composite of
@Controller and @ResponseBody

Controller

@RestController

```
public class PersonController {  
    @Autowired  
    private PersonService personService;  
  
    @GetMapping(value="/person/", produces="application/json")  
    public List<Person> getAll() {  
        return personService.getAll();  
    }  
  
    @GetMapping(value= "/person/{id}", produces = "application/json")  
    public Person get(@PathVariable long id) {  
        return personService.get(id);  
    }  
  
    @PostMapping(value="/person/", consumes = "application/json")  
    public RedirectView post(@RequestBody Person person) {  
        long id = personService.add(person);  
        return new RedirectView("/person/" + id);  
    }  
  
    @PutMapping(value= "/person/{id}", consumes = "application/json")  
    public void put(@PathVariable long id, @RequestBody Person person) {  
        if (id != person.getId()) { throw new IllegalArgumentException(); }  
        personService.update(person);  
    }  
  
    @DeleteMapping("/person/{id}")  
    public void delete(@PathVariable long id) {  
        personService.delete(id);  
    }  
}
```

Produces / Consumes optional

ResponseBody becomes like:
{ "id": 1, "name": "Test", "age": 28 }

RequestBody expected like:
{ "name": "Other", "age": 27 }

RedirectView
"redirect: " String
won't work!

Person & Person Service

```
@JsonIgnoreProperties({"hibernateLazyInitializer"})
@Setter
@Getter
@NoArgsConstructor
@Entity
public class Person {

    @Id
    @GeneratedValue
    private Long id;

    private String name;

    private int age;

}
```

```
public interface PersonService {
    Person get(Long id);
    List<Person> getAll();
    Long add(Person p);
    void update(Person p);
    void delete(Long id);
}
```

```
@Service
@Transactional
public class PersonServiceImpl implements PersonService {
```

```
@Autowired
private PersonRepository personRepository;
```

```
@Override
public Person get(Long id) {
    return personRepository.getOne(id);
}
```

```
@Override
public List<Person> getAll() {
    return personRepository.findAll();
}
```

```
@Override
public Long add(Person p) {
    personRepository.save(p);
    return p.getId();
}
```

```
@Override
public void update(Person p) {
    personRepository.save(p);
}
```

```
@Override
public void delete(Long id) {
    personRepository.deleteById(id);
}
```

Testing

Postman is popular for testing webservice

The screenshot displays the Postman application window. The top bar includes the menu (File, Edit, View, Help), a toolbar with 'New', 'Import', 'Runner', and 'My Workspace' buttons, and a 'Sign In' button. The left sidebar shows a 'History' tab with a list of recent GET requests to 'http://localhost:8080/person/1' and 'http://localhost:8080/person/4'. The main panel is configured for a GET request to 'http://localhost:8080/person/1'. The 'Headers' tab is active, showing two headers: 'Content-Type' and 'Accept', both set to 'application/json'. The 'Body' tab is also visible. The response section at the bottom shows a successful status '200 OK' with a response time of '14 ms' and a size of '161 B'. The response body is displayed in JSON format:

```
{  "id": 1,  "name": "Test",  "age": 28}
```

Postman

File Edit View Help

New Import Runner My Workspace Invite Sign In

	KEY	VALUE	DESCRIPTION	...	Bulk Edit	Prese
<input checked="" type="checkbox"/>	Content-Type	application/json				
<input checked="" type="checkbox"/>	Accept	application/json				
	Key	Value	Description			

Body Cookies Headers (3) Test Results Status: 200 OK Time: 14 ms Size: 161 B

Pretty Raw Preview JSON Save Response

```
1 {
2   "id": 1,
3   "name": "Test",
4   "age": 28
5 }
```

Send / Receive XML

- ▶ Enabling XML is simply adding a dependency

```
<dependency>  
  <groupId>com.fasterxml.jackson.dataformat</groupId>  
  <artifactId>jackson-dataformat-xml</artifactId>  
</dependency>
```

- ▶ With this added our webservice will be able to do both JSON and XML

Content Negotiation

- ▶ HTTP headers are used to indicate what the incoming and outgoing data types should be
 - ▶ **Content-Type** indicates what the browser sends
 - ▶ **Accept** indicates what the browser wants
- ▶ The mime type for XML is:
 - ▶ application/xml

Controller

```
@RestController
public class PersonController {
    @Autowired
    private PersonService personService;

    @GetMapping("/person/")
    public List<Person> getAll() {
        return
            personService.getAll();
    }

    @GetMapping("/person/{id}")
    public Person get(@PathVariable long id) {
        return personService.get(id);
    }

    @PostMapping("/person/")
    public RedirectView post(@RequestBody Person person) {
        long id = personService.add(person);
        return new RedirectView("/person/" + id);
    }

    @PutMapping("/person/{id}")
    public void put(@PathVariable long id, @RequestBody Person person) {
        if (id != person.getId()) { throw new
            IllegalArgumentException(); } personService.update(person);
    }

    @DeleteMapping("/person/{id}")
    public void delete(@PathVariable long
        id) { personService.delete(id);
    }
}
```

By not specifying produces / consumes a controller method can be used for both XML and JSON

Example Receiving

Example Sending

JAXB Mapping

- ▶ The Object to XML Mapping (OXM) defaults to:
 - ▶ Class get its own tag
 - ▶ Every property gets its own tag inside it
 - ▶ An object inside an object is nested
- ▶ If you want to change the name of a tag
 - ▶ Or use an XML attribute
 - ▶ Map them with annotations

Basic OXM Mapping

```
@JacksonXmlRootElement(localName = "Customer")
public class Person {
    @JacksonXmlProperty(isAttribute = true)
    private Long id;
    @JacksonXmlProperty(localName = "firstName")
    private String name;
    private int age;
```

The screenshot shows a REST client interface with the following components:

- Request Bar:** Method `GET`, URL `http://localhost:8080/person/1`, and a `Send` button.
- Headers Tab:** Contains a table of headers:

	KEY	VALUE	DESCRIPTION	...
<input checked="" type="checkbox"/>	Content-Type	application/xml		
<input checked="" type="checkbox"/>	Accept	application/xml		
	key	Value	Description	
- Body Tab:** Shows the XML response:

```
1 <Customer id="1">
2   <age>28</age>
3   <firstName>Test</firstName>
4 </Customer>
```
- Status Bar:** Status: `200 OK`, Time: `35 ms`.

RestTemplate

- Spring provides RestTemplate for REST clients

Method	Description
<code>.getForObject()</code>	Sends a GET, returns a Java Object based on response body
<code>.getForEntity()</code>	Sends a GET, returns ResponseEntity (status/header/body)
<code>.postForLocation()</code>	Sends a POST, returns a URI (Location header from redirect)
<code>.postForObject()</code>	Sends a POST, returns a Java Object based on response body
<code>.postForEntity()</code>	Sends a POST, returns a ResponseEntity (status/header/body)
<code>.put()</code>	Creates or updates a resource using PUT
<code>.patchForObject()</code>	Sends a PATCH, returns Java Object
<code>.delete()</code>	Deletes the resource at the URI using DELETE
<code>.exchange()</code>	General / flexible method using RequestEntity / ResponseEntity

Needs extra HTTP lib to work

Lowerlevel `.execute()` method is also present, which we won't cover

Console Client Config

```
@SpringBootApplication
public class ConsoleConfig {
    @Bean
    public RestTemplate getRestTemplate() {
        return new RestTemplate();
    }

    public static void main(String[] args) {
        SpringApplication.run(ConsoleConfig.class, args);
    }
}
```

Create the RestTemplate bean

Spring Boot executes all beans
that implement CommandLineRunner

```
@Component
public class ConsoleApp implements CommandLineRunner {
    @Autowired
    private PersonService personService;

    @Override
    public void run(String... args) {
        Person p = personService.get(1L);
        personService.add(new Person("Hello", 22));
        System.out.println(personService.getAll());
        p.setAge(33);
        personService.update(p);
        System.out.println(personService.getAll());
        personService.delete(2L);
        System.out.println(personService.getAll());
        p = personService.getAll().get(0);
        System.out.println(p.getName());
    }
}
```

pom.xml dependencies

```
<dependency>
    <groupId>org.springframework.boot</groupId>
    <artifactId>spring-boot-starter</artifactId>
</dependency>
<dependency>
    <groupId>org.springframework</groupId>
    <artifactId>spring-web</artifactId>
</dependency>
```

application.properties

```
spring.main.web-application-type=NONE
```

Example

Same PersonService interface

.getForObject(url, return type, ...path params)

Have to use .exchange() because
.getForObject() cannot specify
List<Person> as return type! (only List)

.exchange(url, method, reqData, respType)

.postForLocation(url, reqData)

.put(url, reqData, ...path params)

.delete(url, ...path params)

@Service

```
public class PersonServiceProxy implements PersonService {
```

```
@Autowired
```

```
private RestTemplate restTemplate;
```

```
private final String personUrl = "http://localhost:8080/person/{id}";
```

```
private final String pplUrl = "http://localhost:8080/person/";
```

```
@Override
```

```
public Person get(Long id) {
```

```
    return restTemplate.getForObject(personUrl, Person.class, id);
```

```
}
```

```
@Override
```

```
public List<Person> getAll() {
```

```
    ResponseEntity<List<Person>> response =  
        restTemplate.exchange(pplUrl, HttpMethod.GET, null,  
            new ParameterizedTypeReference<List<Person>>() {});
```

```
    return response.getBody();
```

```
}
```

```
@Override
```

```
public Long add(Person p) {
```

```
    URI uri = restTemplate.postForLocation(pplUrl, p);
```

```
    if (uri == null) { return null; }
```

```
    Matcher m = Pattern.compile(".*person/(\\d+)").matcher(uri.getPath());  
    m.matches();
```

```
    return Long.parseLong(m.group(1));
```

```
}
```

```
@Override
```

```
public void update(Person p) {
```

```
    restTemplate.put(personUrl, p, p.getId());
```

```
}
```

```
@Override
```

```
public void delete(Long id) {
```

```
    restTemplate.delete(personUrl, id);
```

```
}
```

```
}
```

Summary

- RESTful webservices use HTTP, the most popular data format is JSON (other possible)
- Easy to setup with SpringMVC: include Jackson and use `@ResponseBody` / `@RequestBody`
- RestTemplate provides convenient methods to make calls to RESTful webservices
 - Best to wrap usage inside a service-proxy
